

Renaming Trick

```
In [1]: %matplotlib ipynb
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
from scipy import stats
from matplotlib.backends.backend_pdf import PdfPages
```

In []:

This reads in our well data like normal

```
In [2]: df=pd.read_csv('well_data.csv')
```

To do list

- Open the r2 excel file you made in class. I called it r2_class_example.xlsx
- add a new column. Call it something like new_name. Give it new names.
- Save the file to a new name so it can't get over written. I called it r2_class_example_new_names.xlsx
- read it in and call it something useful
- set the index column to name.

```
In [5]: df_name=pd.read_excel('r2_class_example_new_names.xlsx', index_col='name')
```

In [6]: df_name

```
Out[6]:
```

	Unnamed: 0	r2	new_name
name			
Sr	11	0.155595	Stronitum (pp=b)
Ca	3	0.154148	Calcium (ppb)
P	1	0.069488	Phosphourous (ppm)
Fe	4	0.065557	Fe (mgL ^{^{-1}})
Ba	5	0.059968	ppm
Na	6	0.053342	Sodium is boring
Si	0	0.037977	Si (ppb)
Mn	9	0.032770	I hate units!
SO4	14	0.021915	ppm
Br	15	0.018130	ppm
S	2	0.014789	Sulfur $\left(\frac{\mu\text{g}}{\text{L}}\right)$
Cl	13	0.009093	ppb
Mg	7	0.000824	ppm
K	8	0.000090	something else?
F	12	0.000030	ppm

Here is what we can do.

- We can pass the element name into df_name and try to get out the new name.
- below is my bad schematic of using a dataframe as a converter.
- We do this by asking for the new_name column and passing in the index.
- There are a couple ways to do this.

```
In [8]: from IPython.display import Image
Image(filename='converter.jpg',width=500)
```

Out [8]:

```
In [9]: el='Fe'

df_name['new_name'][el]
```

```
Out[9]: 'Fe (mgL$^{-1}$)'
```

```
In [10]: el='Fe'
df_name.loc[el]['new_name']
```

```
Out[10]: 'Fe (mgL$^{-1}$)'
```

Now change el to a different element.

```
In [11]: el='Ca'
df_name.loc[el]['new_name']
```

```
Out[11]: 'Calcium (ppb)'
```

Now this is confusing.

- loop over the columns in df
- check if the column name is in the index of df_name
- if yes print the old and new name

```
In [12]: for col in df:
         if col in df_name.index:
             print('The original column name is {} and now I can convert it to {}'.format(col, df_name.loc[col]['new_name']))
         else:
             print('not in index')
```

```
not in index
not in index
not in index
not in index
not in index
The original column name is Si and now I can convert it to Si (ppb)
The original column name is P and now I can convert it to Phosphorous (ppm)
The original column name is S and now I can convert it to Sulfur  $\left(\frac{\mu g}{L}\right)$ 
The original column name is Ca and now I can convert it to Calcium (ppb)
The original column name is Fe and now I can convert it to Fe (mgL$^{-1}$)
The original column name is Ba and now I can convert it to ppm
The original column name is Na and now I can convert it to Sodium is boring
The original column name is Mg and now I can convert it to ppm
The original column name is K and now I can convert it to something else?
The original column name is Mn and now I can convert it to I hate units!
not in index
The original column name is Sr and now I can convert it to Strontium (pp=b)
The original column name is F and now I can convert it to ppm
The original column name is Cl and now I can convert it to ppb
The original column name is SO4 and now I can convert it to ppm
The original column name is Br and now I can convert it to ppm
```

Now here I am going to use the trick to change an axis name

```

In [13]: fig,ax=plt.subplots()

x='As'
y='Fe'

props=dict(boxstyle='round',facecolor='coral',alpha=0.5)
print (y)

if df[y].dtype==float:
    ax.scatter(df[x],df[y])
    ax.set_xlabel(x,fontsize=14)
    ax.set_ylabel(df_name.loc[y]['new_name'], fontsize=14)

    results=stats.linregress(df[[x,y]].dropna())

    textstr='m={:.3f}\nb={:.3f}\n$r^2$={:.3f}\n$p$={:.3f}'.\
            format(results.slope,results.intercept\
                    ,results.rvalue**2,results.pvalue)

    x_fit=np.array([df[x].min(),df[x].max()])
    ax.plot(x_fit,results.slope*x_fit+results.intercept,color='gray',linestyle='dotted')

    ax.text(0.75,0.95,textstr,transform=ax.transAxes,fontsize=14\
            ,verticalalignment='top',bbox=props)

```

Fe
